# Update on AIMS

- AIMS is now publicly available:
  - September 2015: version 1.0
  - April 2016: version 1.1
- more and more users:
  - Birmingham, Meudon, Porto ...
  - solar-like stars, red giants?
  - discover bugs and improve the code

# AIMS in a nutshell

## Analytical priors & Observational constraints:

- seismic:  $v_i$ ,  $r_{02}$ ,  $r_{01}$ ,  $r_{10}$ ,  $\Delta v$
- classical:  $T_{\text{eff}}$ ,  $L$ ,  $[M/H]$ , ...
- error bars and correlations

## Grid of models

- n-dimensional ( $n \geq 3$ )
- pre-computed pulsation frequencies
- optional surface effects

## AIMS = “Astero seismic Inference on a Massive Scale”

- unstructured linear interpolation
- MCMC approach with parallel tempering (via the python EMCEE package, Foreman-Mackey et al. 2013)

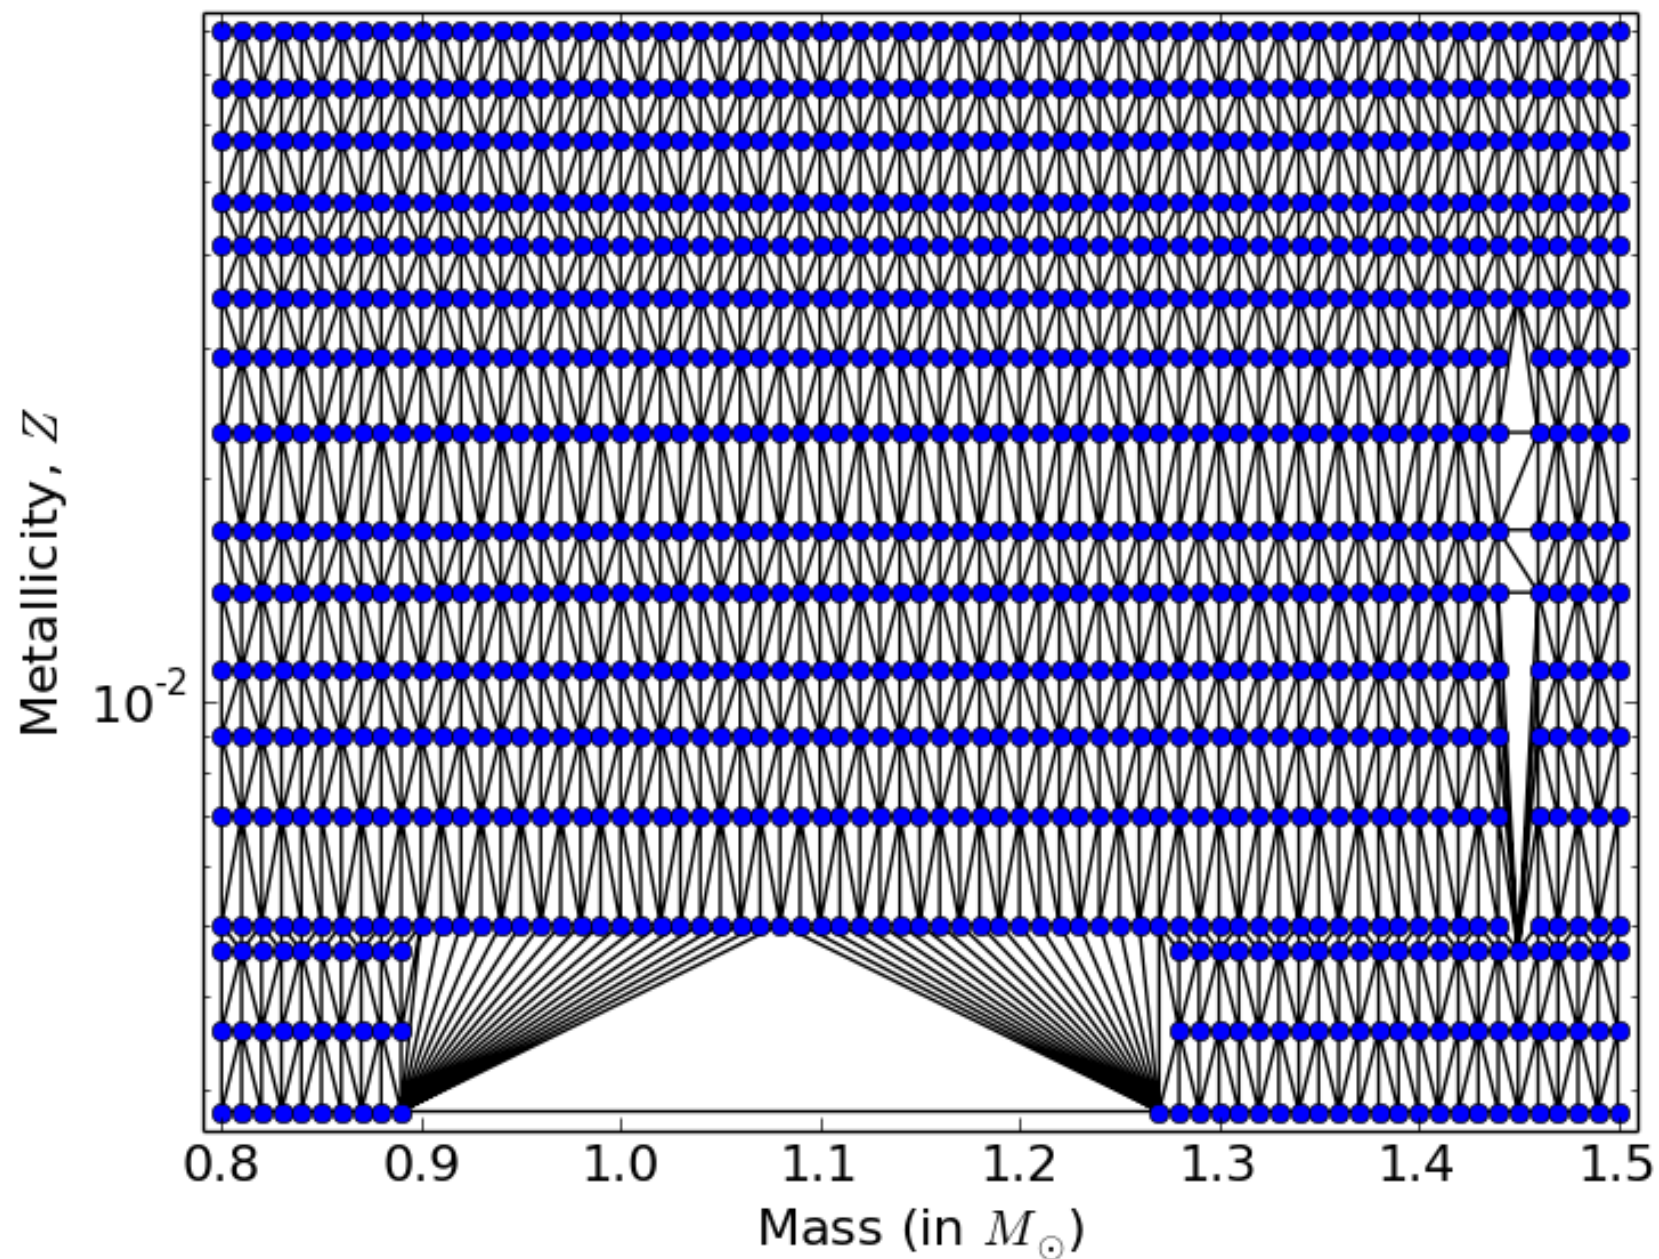

## Estimated properties

- probability distribution functions for different parameters

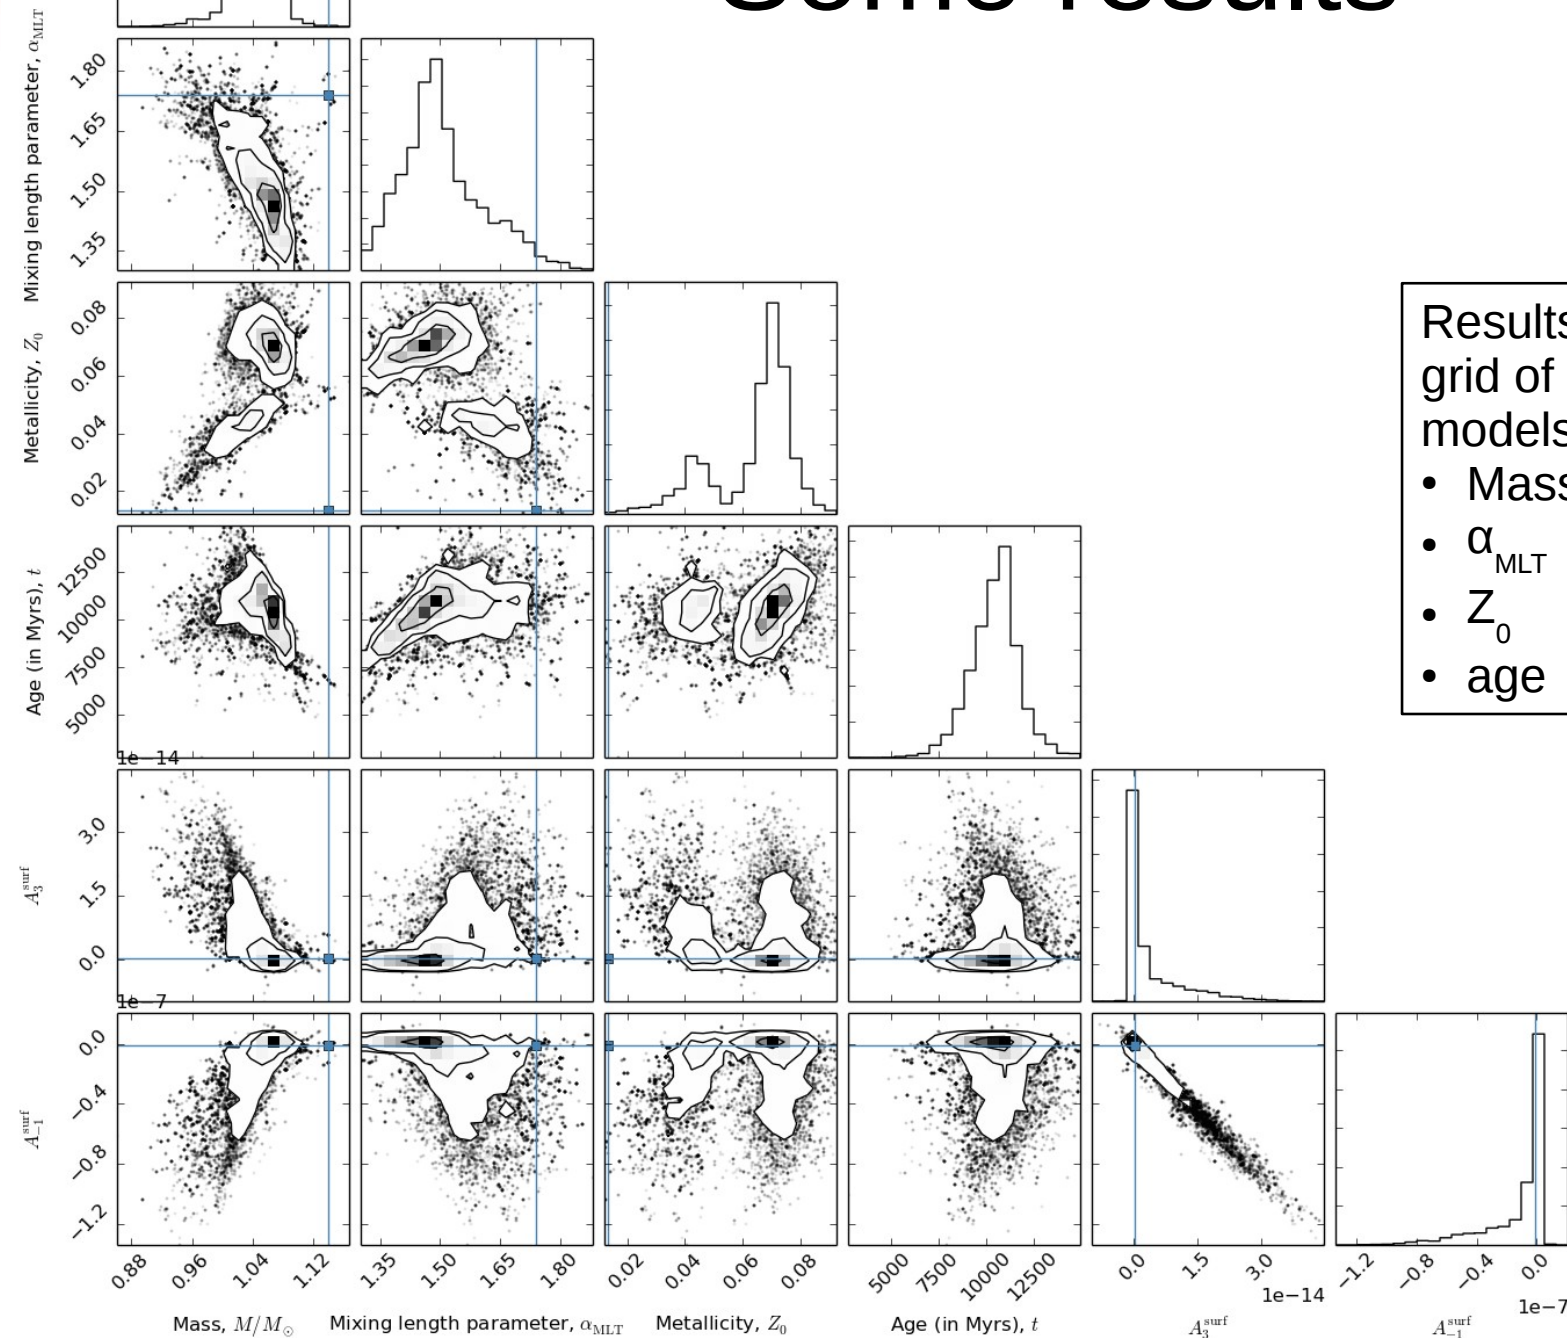

## Representative models

- provides coefficients for interpolating acoustic structure
- allows inversions

# Grid tessellation

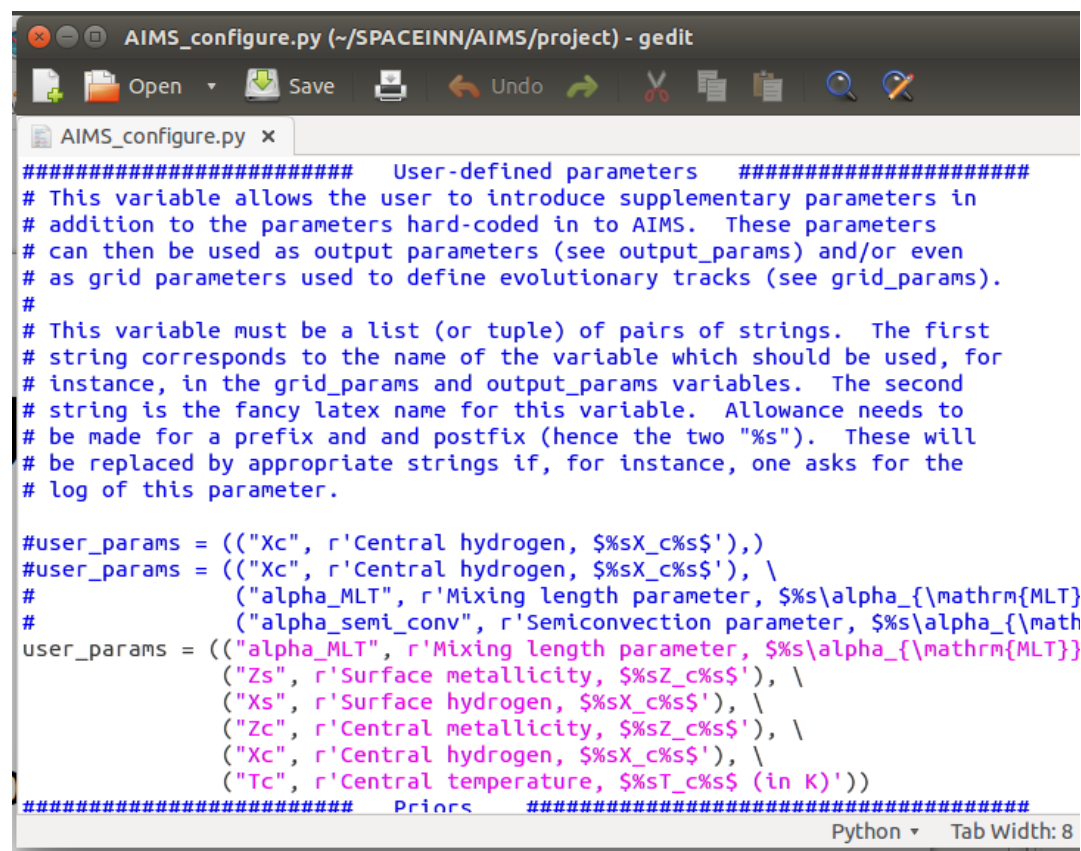

# Some results

# What has changed in version 1.1?

- extrapolation beyond the edge of the grid is now possible
  - this can cause other problems, as recently discovered
- the user can easily introduce new grid parameters

```

##### User-defined parameters #####
# This variable allows the user to introduce supplementary parameters in
# addition to the parameters hard-coded in to AIMS. These parameters
# can then be used as output parameters (see output_params) and/or even
# as grid parameters used to define evolutionary tracks (see grid_params).
#
# This variable must be a list (or tuple) of pairs of strings. The first
# string corresponds to the name of the variable which should be used, for
# instance, in the grid_params and output_params variables. The second
# string is the fancy latex name for this variable. Allowance needs to
# be made for a prefix and postfix (hence the two "%s"). These will
# be replaced by appropriate strings if, for instance, one asks for the
# log of this parameter.

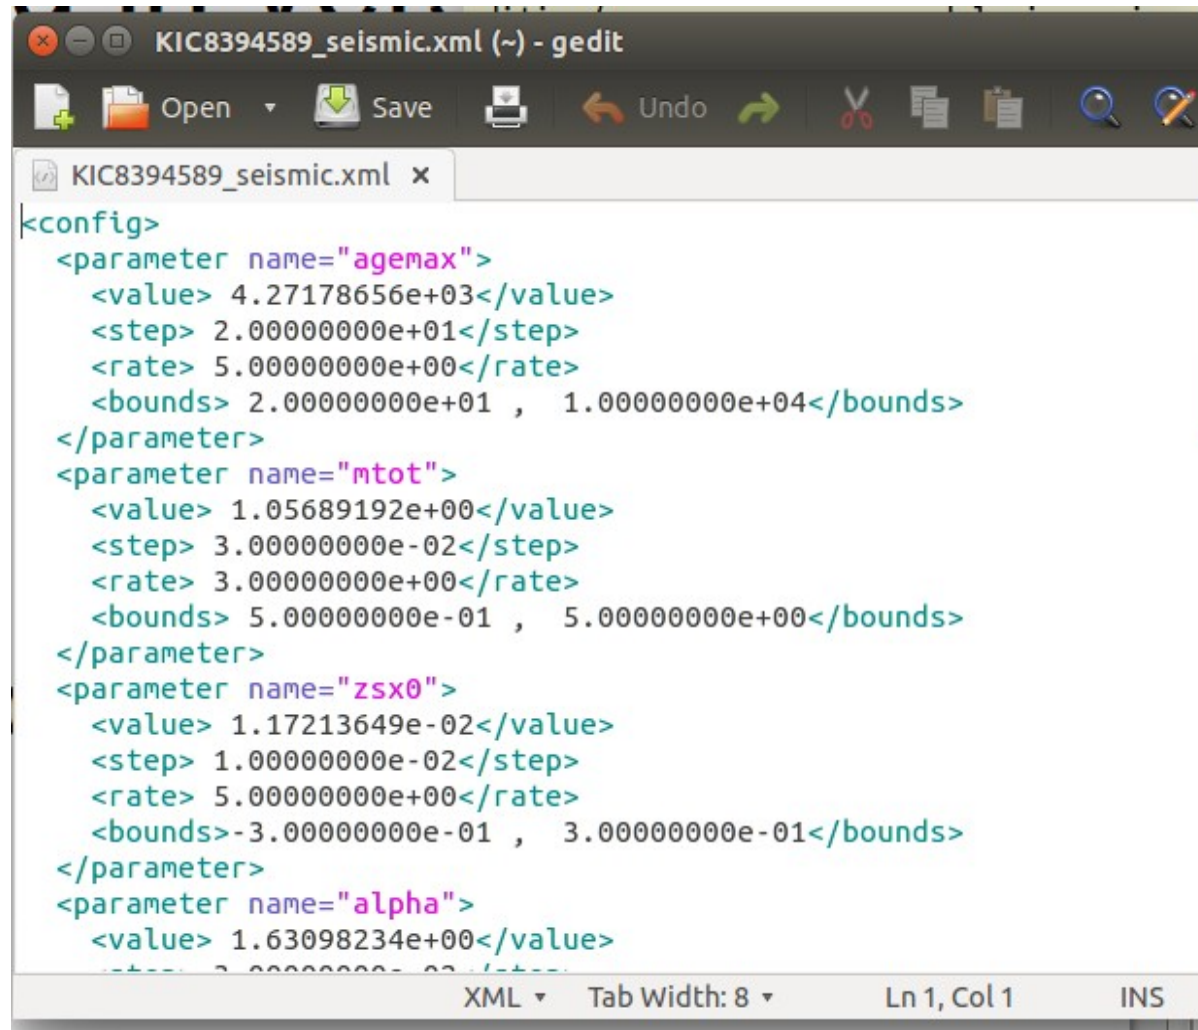

#user_params = (("Xc", r'Central hydrogen, %sX_c%s'),)
#user_params = (("Xc", r'Central hydrogen, %sX_c%s'), \
#               ("alpha_MLT", r'Mixing length parameter, %s\alpha_{\mathrm{MLT}}'), \
#               ("alpha_semi_conv", r'Semiconvection parameter, %s\alpha_{\mathrm{semi_conv}}'))
user_params = (("alpha_MLT", r'Mixing length parameter, %s\alpha_{\mathrm{MLT}}'), \
               ("Zs", r'Surface metallicity, %sZ_c%s'), \
               ("Xs", r'Surface hydrogen, %sX_c%s'), \
               ("Zc", r'Central metallicity, %sZ_c%s'), \
               ("Xc", r'Central hydrogen, %sX_c%s'), \
               ("Tc", r'Central temperature, %sT_c%s$ (in K)'))

##### Priors #####
    
```

# Ongoing and future improvements

- inputs/outputs:
  - read binary frequency files from ADIPLS
  - write XML files to be used with OSM (Master's work by B. Herbert)
- numerical aspects
  - speed up various parts using fortran or c?

# XML file produced by AIMS

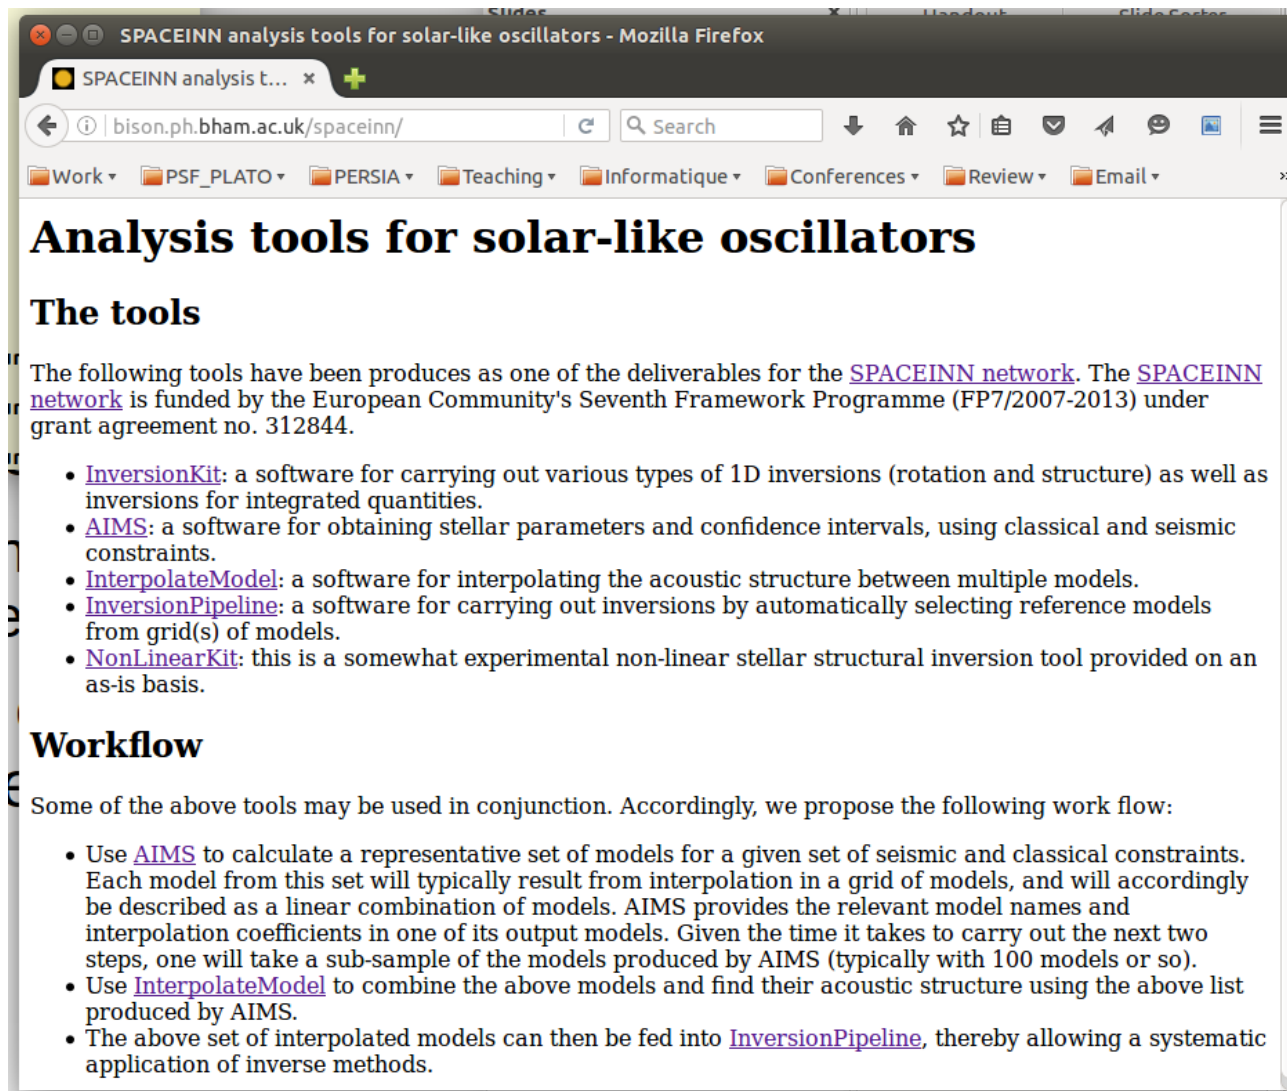

```

## Analysis tools for solar-like oscillators

### The tools

The following tools have been produced as one of the deliverables for the [SPACEINN network](#). The [SPACEINN network](#) is funded by the European Community's Seventh Framework Programme (FP7/2007-2013) under grant agreement no. 312844.

- [InversionKit](#): a software for carrying out various types of 1D inversions (rotation and structure) as well as inversions for integrated quantities.
- [AIMS](#): a software for obtaining stellar parameters and confidence intervals, using classical and seismic constraints.
- [InterpolateModel](#): a software for interpolating the acoustic structure between multiple models.
- [InversionPipeline](#): a software for carrying out inversions by automatically selecting reference models from grid(s) of models.
- [NonLinearKit](#): this is a somewhat experimental non-linear stellar structural inversion tool provided on an as-is basis.

### Workflow

Some of the above tools may be used in conjunction. Accordingly, we propose the following work flow:

- Use [AIMS](#) to calculate a representative set of models for a given set of seismic and classical constraints. Each model from this set will typically result from interpolation in a grid of models, and will accordingly be described as a linear combination of models. AIMS provides the relevant model names and interpolation coefficients in one of its output models. Given the time it takes to carry out the next two steps, one will take a sub-sample of the models produced by AIMS (typically with 100 models or so).
- Use [InterpolateModel](#) to combine the above models and find their acoustic structure using the above list produced by AIMS.
- The above set of interpolated models can then be fed into [InversionPipeline](#), thereby allowing a systematic application of inverse methods.

# Inversion workflow

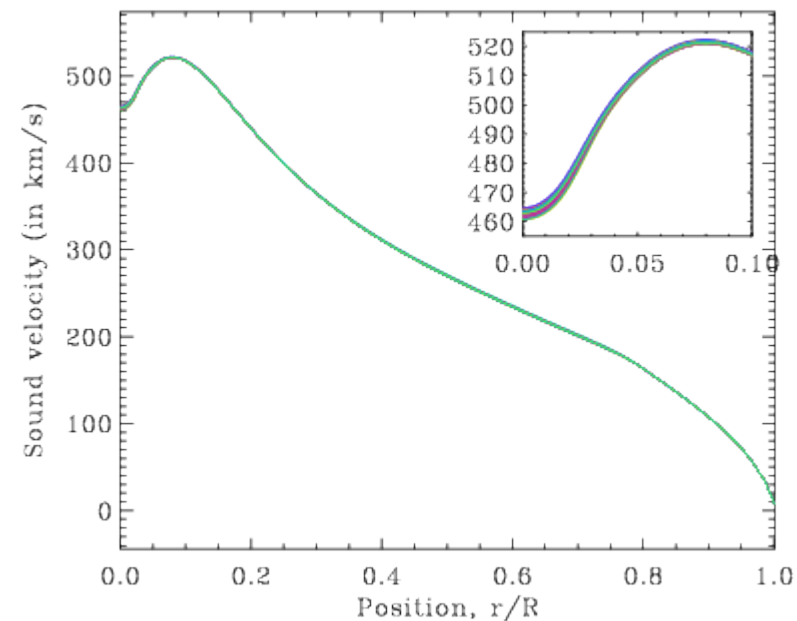

**AIMS**

**Interpolate Model**

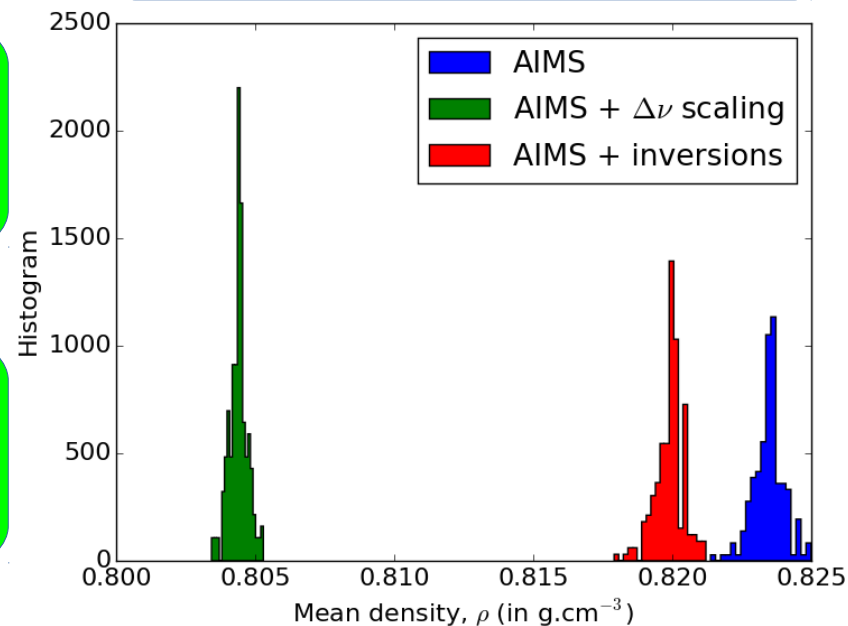

**Inversion Pipeline**

**Stellar properties**

Interpolated models

Stellar properties

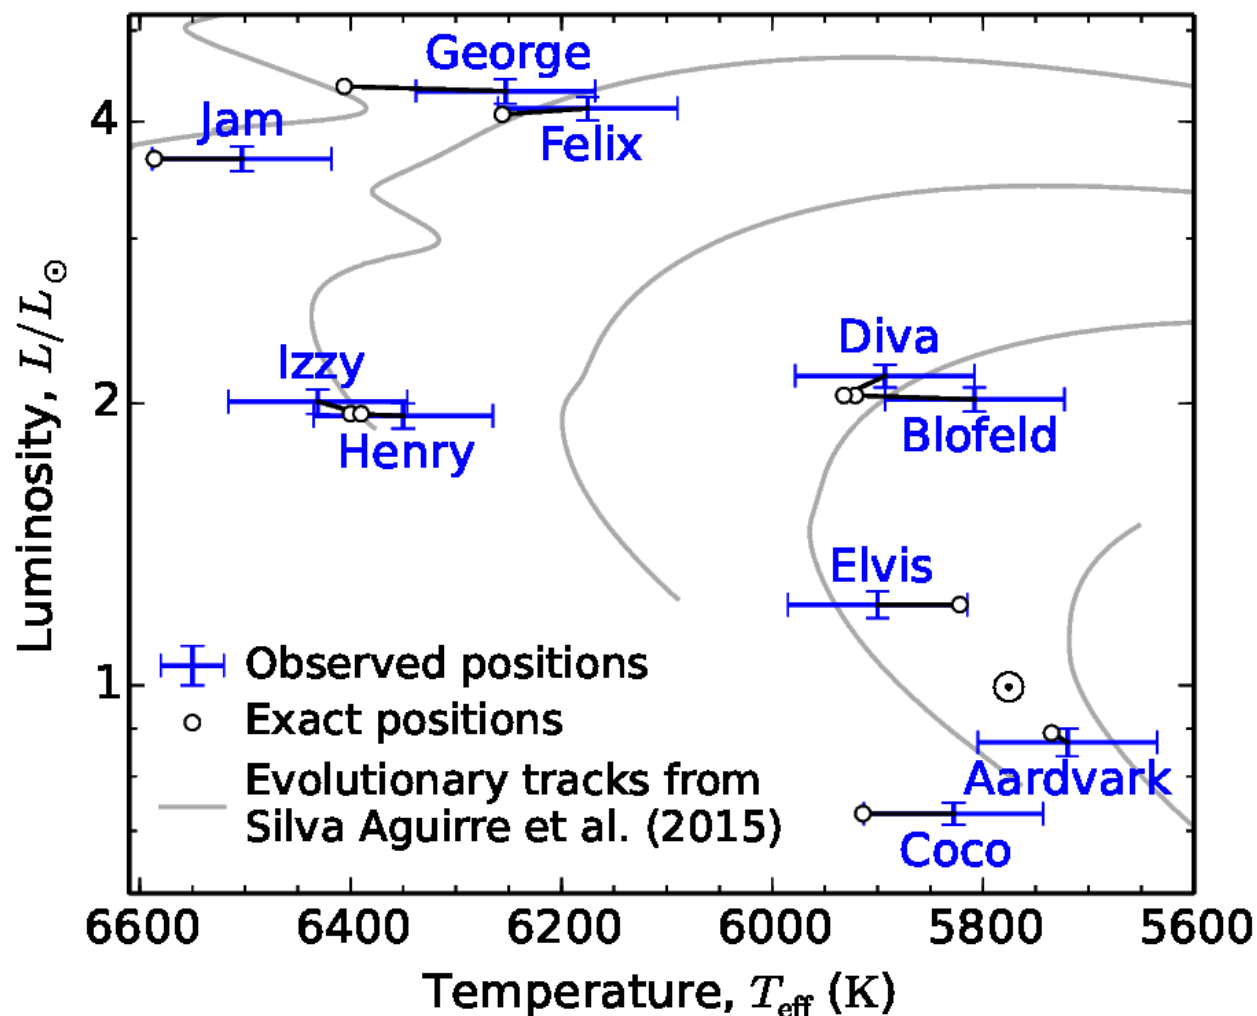

See poster from KASC/TASC conference (Aarhus, 2015)

# SpaceINN hare-and-hounds article

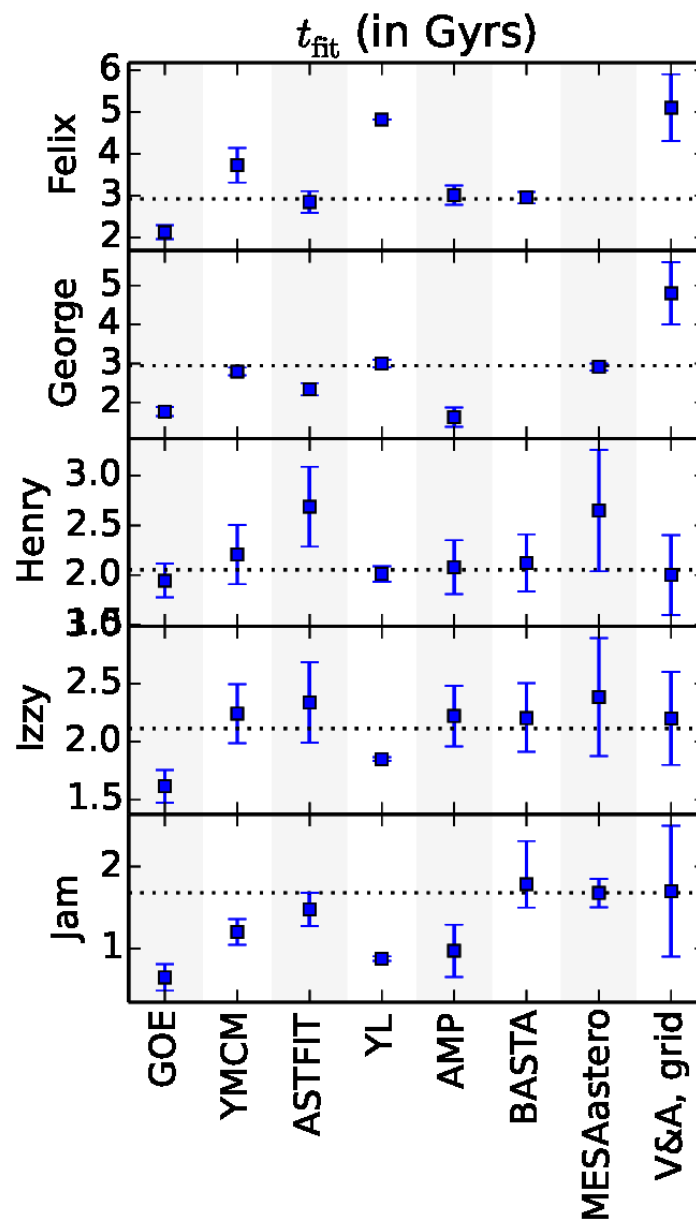

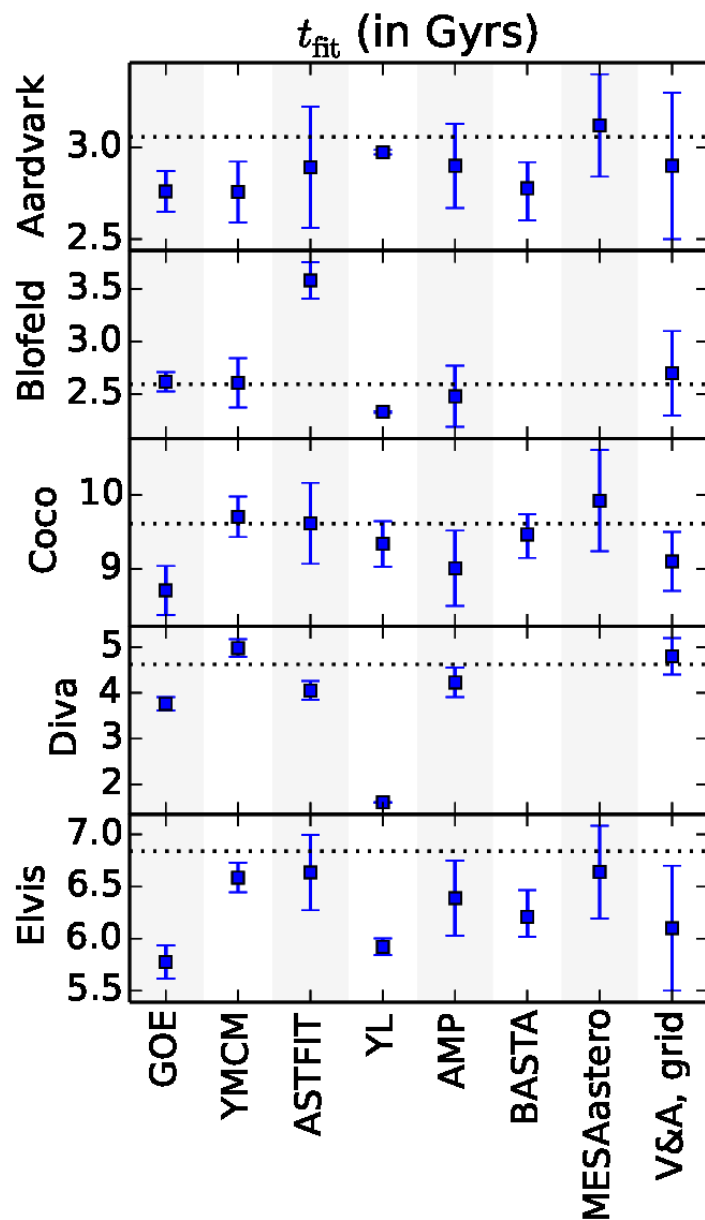

- number of participants: 4 hares + 14 hounds
- various methods applied by the hounds:
  - grid (or forward) modelling
  - glitch fitting
  - misc.: inversions, scaling laws
- accepted for publication in A&A
  - arXiv: [astro-ph.SR/1604.08404](https://arxiv.org/abs/1604.08404)

# The stellar targets

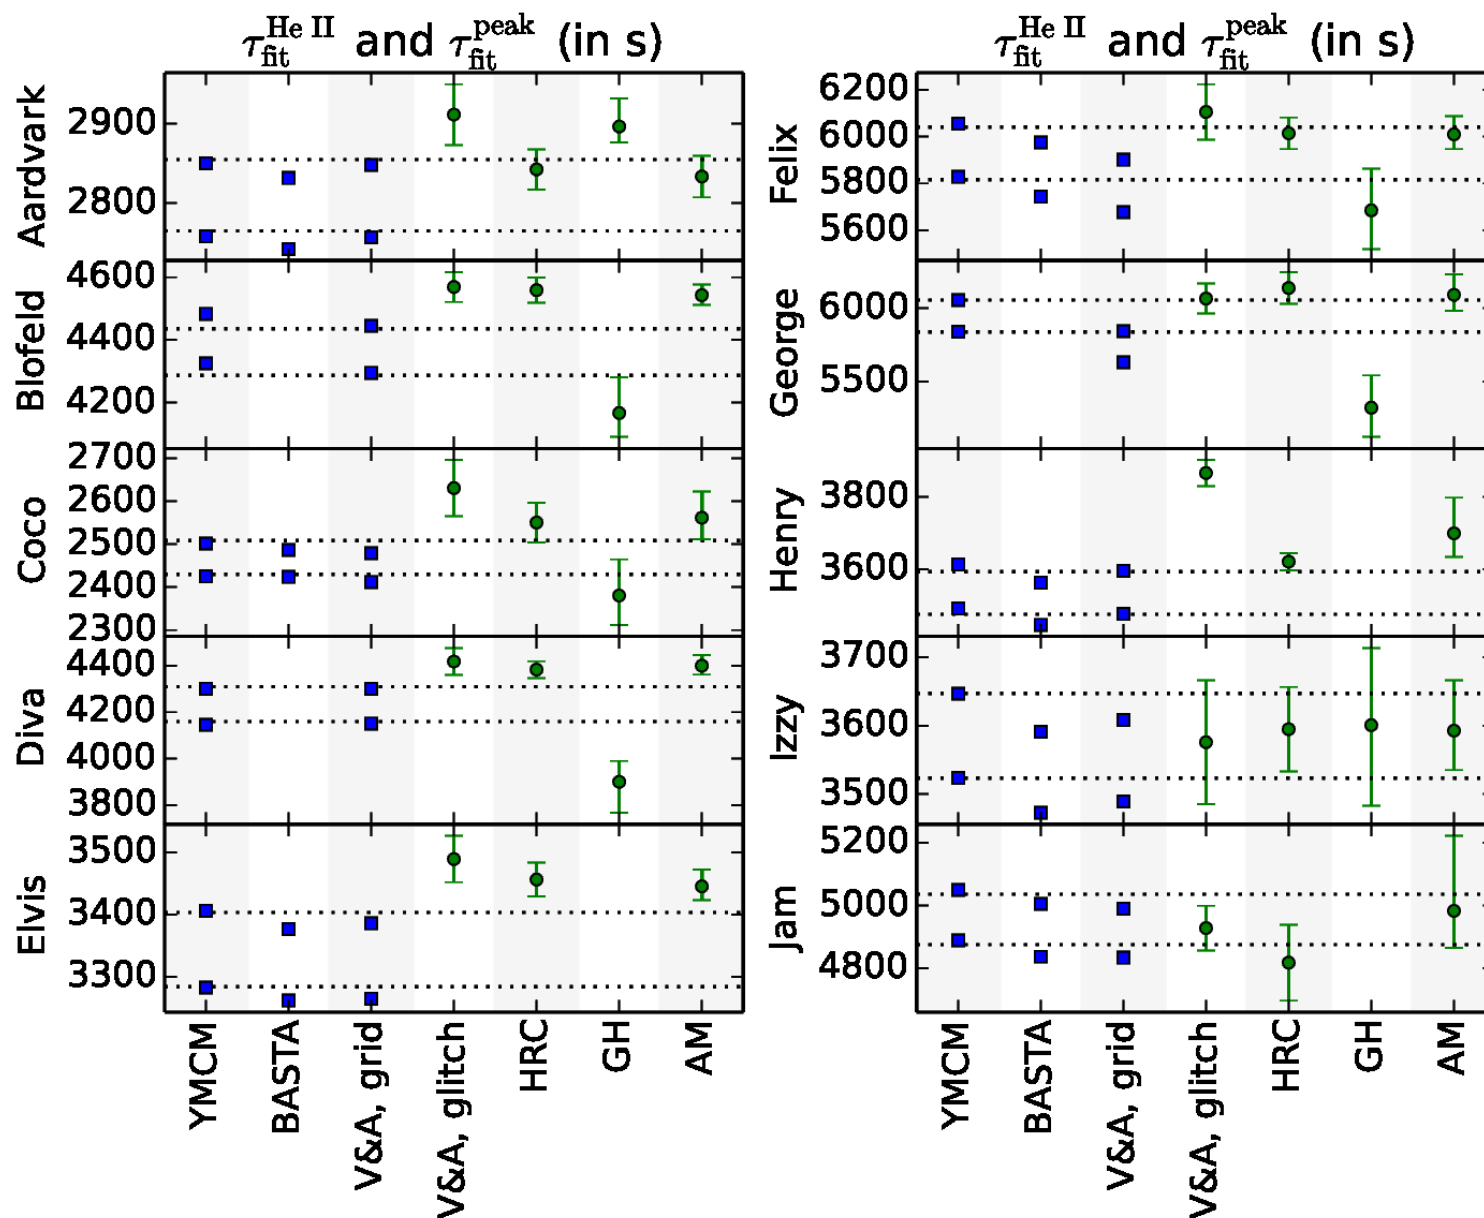

$0.78 - 1.33 M_{\odot}$ ;  $0.82 - 1.72 R_{\odot}$ ,  $1.7 - 9.6$  Gyrs

# Some results

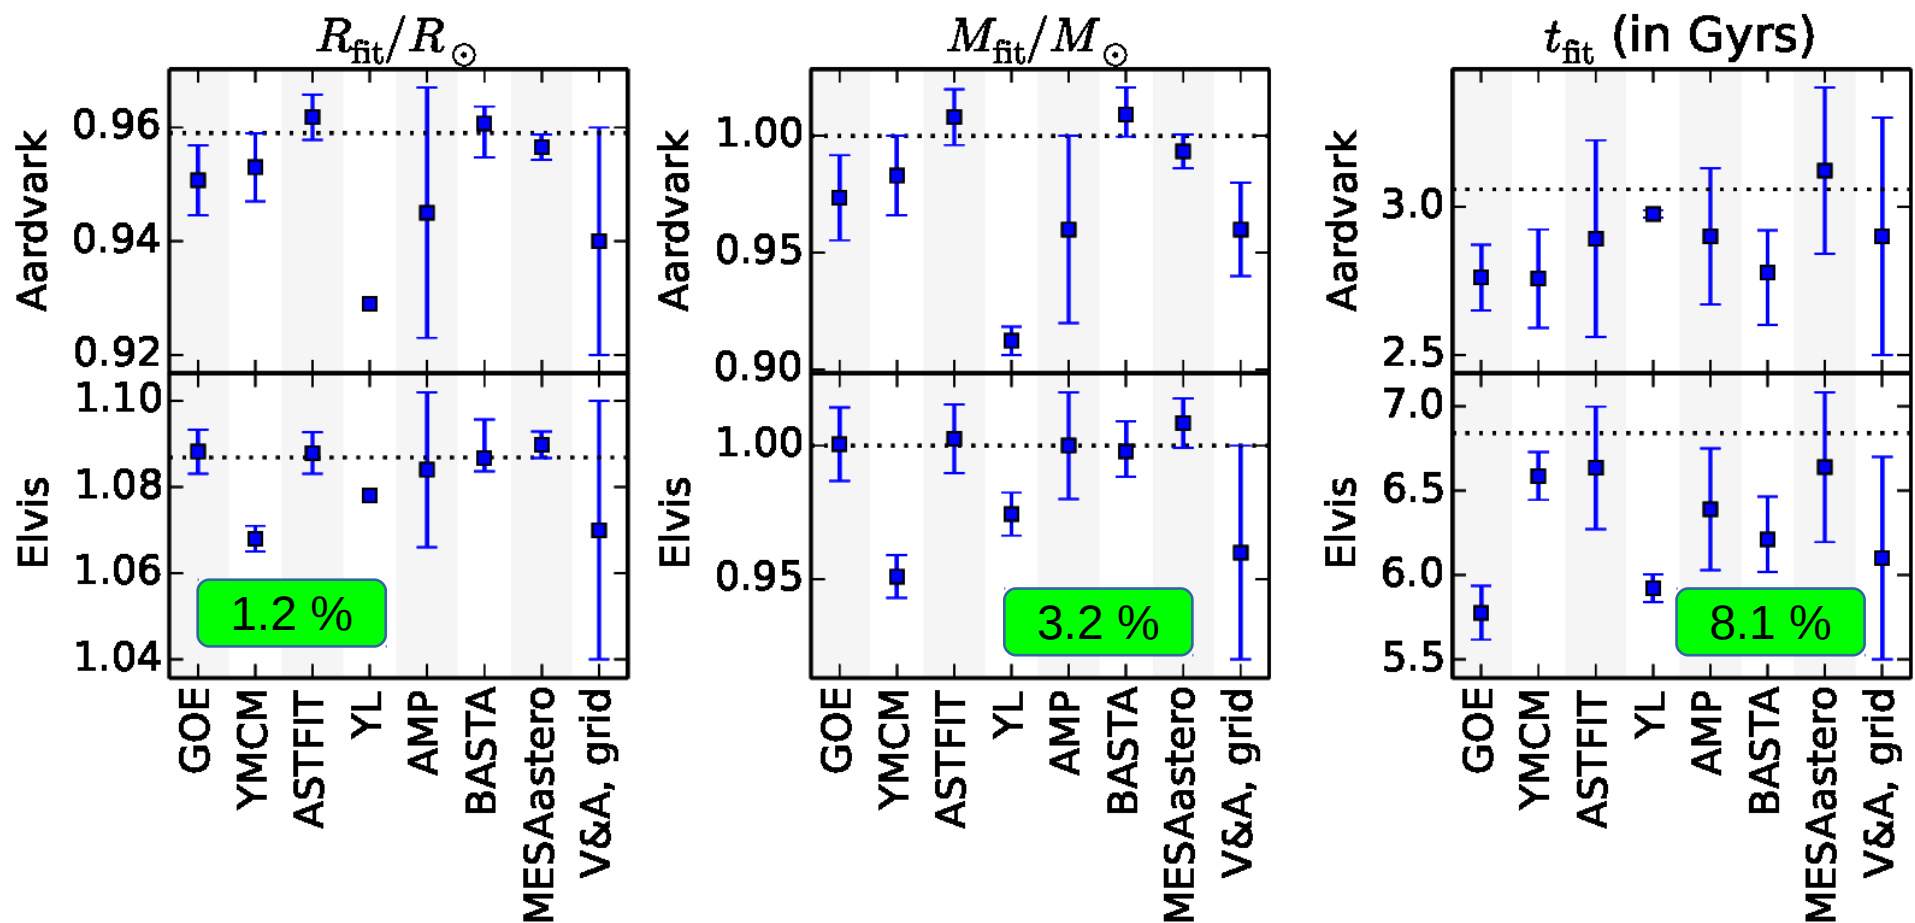

23 % overall accuracy

# Some results

~ 2 % overall accuracy

# Results for the 1.0 $M_{\odot}$ stars

Compliant with PLATO 2.0 requirements

# Main conclusions

- forward modelling
  - most accurate
  - very model dependant
- glitch analysis
  - more model independent
  - complement forward modelling
- error bars
  - global methods (grid, bayesian, genetic algorithms ...) more robust than local methods (Levenberg-Marquardt)
- limitations of the exercise (based on models only)
